Mathematical tools

- Linear Algebra
- Projective geometry
- Optimization
- Deep learning

Course contents and lecturers

Projective geometry and image transformations	Gloria Haro
Camera models, the geometry of one view	Coloma Ballester
Camera calibration. Pose estimation	Gloria Haro
The geometry of two views	Javier Ruiz
Structure and depth computation	Gloria Haro
New view synthesis	Gloria Haro
Multi-view stereo	Antonio Agudo
Structure from motion	Antonio Agudo
3D sensors	Josep Ramon Casas

Projective geometry

Projective geometry

Objects in the 3D world are transformed into image objects through a **projective transformation**.

Geometric properties not preserved: lengths (distances), angles, distance ratio.
What is preserved? straight lines (collinearity), cross ratio (ratio of ratio of lengths).

Image source: [Hartley Zisserman 2004]

Projective geometry

School of Athens. Raphael, 1509-1511.

Image source: [Wikipedia]

Projective geometry

Why projective geometry?

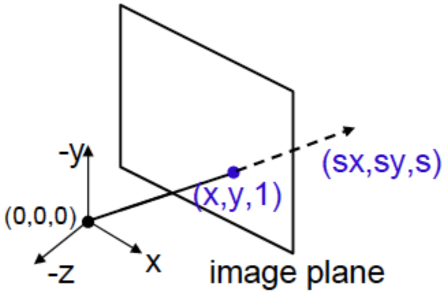
- The image capture of the camera is described with a linear transformation.
- The intersection of two lines and the line that passes through two points is a linear operation.
- Points at infinity have a natural representation.

We will study:

- **2D projective geometry:** It allows to remove the projective distortion of flat objects and build image mosaics (panoramas).
- **3D projective geometry:** It models the camera projection and allows the 3D reconstruction, the calibration and auto-calibration.

The projective plane

A point in the image is a **ray** in the projective space.



Each point (x, y) on the (image) plane is represented by a ray: (sx, sy, s), the **visual ray**, **visual direction** or **view direction**.

All points on the ray are equivalent: $(x, y, 1) \equiv (sx, sy, s)$
$(s \in \mathbb{R},\ s \neq 0!)$

Image source: [S. Seitz]

The projective plane

Notation: $\mathbb{P}^2$, **projective space of dimension 2** (the projective plane)

1. Representation of points:

- Points in the 2D Euclidean space $\mathbb{R}^2$:
  $$(x, y)^T = \begin{pmatrix} x \\ y \end{pmatrix} \text{ cartesian coordinates}$$
- Points in the 2D projective space $\mathbb{P}^2$:
  $$\mathbf{x} = (x_1, x_2, x_3)^T = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \text{ homogeneous coordinates}$$

The projective plane

Notation: $\mathbb{P}^2$, **projective space of dimension 2** (the projective plane)

1. Representation of points:

- Points in the 2D Euclidean space $\mathbb{R}^2$:
  $$(x, y)^T = \begin{pmatrix} x \\ y \end{pmatrix} \text{ cartesian coordinates}$$
- Points in the 2D projective space $\mathbb{P}^2$:
  $$\mathbf{x} = (x_1, x_2, x_3)^T = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \text{ homogeneous coordinates}$$

Given $\mathbf{x}$ and $\mathbf{x}' \in \mathbb{P}^2$, we define the **equivalence relationship** as:

$$\mathbf{x} \equiv \mathbf{x}' \text{ (or } \mathbf{x} \sim \mathbf{x}' \text{), if } \exists\, \lambda \neq 0 \text{ such that } \mathbf{x} = \lambda \mathbf{x}'.$$

The projective plane

Notation: $\mathbb{P}^2$, **projective space of dimension 2** (the projective plane)

1. Representation of points:

- Points in the 2D Euclidean space $\mathbb{R}^2$:

$$(x, y)^T = \begin{pmatrix} x \\ y \end{pmatrix} \quad \textbf{cartesian coordinates}$$

- Points in the 2D projective space $\mathbb{P}^2$:

$$\mathbf{x} = (x_1, x_2, x_3)^T = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \quad \textbf{homogeneous coordinates}$$

Given $\mathbf{x}$ and $\mathbf{x}' \in \mathbb{P}^2$, we define the **equivalence relationship** as:

$$\mathbf{x} \equiv \mathbf{x}' \text{ (or } \mathbf{x} \sim \mathbf{x}' \text{), if } \exists\, \lambda \neq 0 \text{ such that } \mathbf{x} = \lambda \mathbf{x}'.$$

We represent a point of the plane $\mathbb{R}^2$ by a vector $\mathbf{x}$ in $\mathbb{R}^3 \setminus \{(0,0,0)\}$.

The projective plane

How do we transform from cartesian to homogeneous coord. $(\mathbb{R}^2 \rightarrow \mathbb{P}^2)$?

$$(x, y)^T \rightarrow (x, y, 1)^T$$

The projective plane

How do we transform from cartesian to homogeneous coord. $(\mathbb{R}^2 \to \mathbb{P}^2)$?

$$(x, y)^T \to (x, y, 1)^T$$

How do we transform from homogeneous to cartesian coord. $(\mathbb{P}^2 \to \mathbb{R}^2)$?

$$(x_1, x_2, x_3)^T \to \underbrace{\left(\frac{x_1}{x_3}, \frac{x_2}{x_3}\right)^T}_{\text{we need } x_3 \neq 0!} = \underbrace{\left(\frac{sx}{s}, \frac{sy}{s}\right)^T}_{(x_1, x_2, x_3)^T = (sx, sy, s)^T} = (x, y)^T$$

The projective plane

How do we transform from cartesian to homogeneous coord. $(\mathbb{R}^2 \to \mathbb{P}^2)$?

$$(x, y)^T \to (x, y, 1)^T$$

How do we transform from homogeneous to cartesian coord. $(\mathbb{P}^2 \to \mathbb{R}^2)$?

$$(x_1, x_2, x_3)^T \to \underbrace{\left(\frac{x_1}{x_3}, \frac{x_2}{x_3}\right)^T}_{\text{we need } x_3 \neq 0!} = \underbrace{\left(\frac{sx}{s}, \frac{sy}{s}\right)^T}_{(x_1, x_2, x_3)^T = (sx, sy, s)^T} = (x, y)^T$$

We require $x_3 \neq 0$
$\Rightarrow$ points in $\mathbb{P}^2$ with $x_3 = 0$ **do not have an equivalent** in $\mathbb{R}^2$,
these represent **points at infinity**.

The projective plane

2. Representation of lines:

Given $(x, y)^T$ a point in the plane $\mathbb{R}^2$, the equation of the line that passes through the point is:

$$ax + by + c = 0, \quad a, b, c \in \mathbb{R}.$$

The projective plane

2. Representation of lines:

Given $(x,y)^T$ a point in the plane $\mathbb{R}^2$, the equation of the line that passes through the point is:

$$ax + by + c = 0, \quad a, b, c \in \mathbb{R}.$$

If $\mathbf{x} = (x, y, 1)^T$ and $\ell = (a, b, c)^T$ we have that the line equation can be writen as:

$$\langle \ell, \mathbf{x} \rangle = 0, \text{ or } \ell^T \mathbf{x} = 0, \text{ or } \mathbf{x}^T \ell = 0.$$

(Note: it holds also for $\mathbf{x}' = s\mathbf{x}$)

$\ell = (a, b, c)^T \in \mathbb{R}^3 \setminus \{(0,0,0)\}$ represents a line in $\mathbb{P}^2$,

line in homogeneous coordinates.

The projective plane

2. Representation of lines:

Given $(x, y)^T$ a point in the plane $\mathbb{R}^2$, the equation of the line that passes through the point is:

$$ax + by + c = 0, \quad a, b, c \in \mathbb{R}.$$

If $\mathbf{x} = (x, y, 1)^T$ and $\ell = (a, b, c)^T$ we have that the line equation can be writen as:

$$\langle \ell, \mathbf{x} \rangle = 0, \text{ or } \ell^T \mathbf{x} = 0, \text{ or } \mathbf{x}^T \ell = 0.$$

(Note: it holds also for $\mathbf{x}' = s\mathbf{x}$)

$\ell = (a, b, c)^T \in \mathbb{R}^3 \setminus \{(0, 0, 0)\}$ represents a line in $\mathbb{P}^2$,
line in homogeneous coordinates.

Equivalent representations:

$$\ell \equiv \ell' \text{ if } \exists k \neq 0 \text{ such that } \ell = k\ell'.$$

The projective plane

Consider the line $\ell = (a, b, c)^T$ $(ax + by + c = 0)$,
the **point at infinity of the line** is $(-b, a, 0)^T$.

The projective plane

Consider the line $\ell = (a, b, c)^T$ $(ax + by + c = 0)$,
the **point at infinity of the line** is $(-b, a, 0)^T$.

Points of the type $(x_1, x_2, 0)^T$ represent points at infinity: they are called **ideal points**.

The projective plane

Consider the line $\ell = (a, b, c)^T$ $(ax + by + c = 0)$,
the **point at infinity of the line** is $(-b, a, 0)^T$.

Points of the type $(x_1, x_2, 0)^T$ represent points at infinity: they are called **ideal points**.
The plane Π_0 represents the points at infinity of all the lines:

$$\Pi_0 = \{(x_1, x_2, 0)^T : (x_1, x_2) \neq (0, 0)\}$$

.
Then, we can write:

$$\mathbb{P}^2 = \underbrace{\{(x_1, x_2, x_3)^T \in \mathbb{R}^3 : x_3 \neq 0\}}_{\text{classic points}} \cup \underbrace{\Pi_0}_{\text{ideal points}} = \mathbb{R}^3 \setminus \{(0, 0, 0)\}$$

The projective plane

Intersection of two lines

Consider the lines $\ell = (a, b, c)^T$ and $\ell' = (a', b', c')^T$, their **intersection point** $\mathbf{x}$ is:

$$\mathbf{x} = \ell \times \ell'.$$

Recall: the cross product

$$\ell \times \ell' = \begin{vmatrix} i & j & k \\ a & b & c \\ a' & b' & c' \end{vmatrix} = (bc' - b'c, a'c - ac', ab' - a'b).$$

The projective plane

The intersection of two parallel lines

The lines $\ell = (a, b, c)^T$ and $\ell' = (a, b, c')^T$ are parallel, they have the same slope $-a/b$.

Their intersection point is

$$\ell \times \ell' = (bc' - bc, ac - ac', 0)^T \Rightarrow \text{ a point at infinity.}$$

If $c \neq c'$ then $(bc' - bc, ac - ac', 0)^T \equiv (-b, a, 0)^T$

The projective plane

The line that joins two points

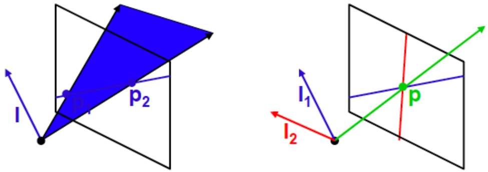
Consider the points $\mathbf{x} = (x_1, x_2, x_3)^T$ and $\mathbf{x}' = (x_1', x_2', x_3')^T$,

the **line that passes through the two points** is:

$$\ell = \mathbf{x} \times \mathbf{x}'.$$

Point and line duality

A line ℓ is perpendicular to every point (ray) $\mathbf{p}$ on the line: $\ell^T \mathbf{p} = 0$



The line ℓ spanned by rays $\mathbf{p_1}$ and $\mathbf{p_2}$: $\Rightarrow \ell = \mathbf{p_1} \times \mathbf{p_2}$

- ℓ is perpendicular to $\mathbf{p_1}$ and $\mathbf{p_2}$
- ℓ is the plane normal

The point $\mathbf{p}$ intersection of two lines ℓ_1 and ℓ_2:

- $\mathbf{p}$ is perpendicular to ℓ_1 and ℓ_2: $\Rightarrow \mathbf{p} = \ell_1 \times \ell_2$

Points and lines are **dual** in the projective space: given any formula, the meanings of points and lines can be switched to get another formula.

Image source: [S. Seitz]

The projective plane

Duality

Given any formula, the meaning of points and lines can be switched to get another valid formula.

Ex: $\mathbf{x} = \ell \times \ell'$ and $\ell = \mathbf{x} \times \mathbf{x}'$

Ex: Exists a single point that joins two lines, and exists a single point intersecting two lines.

The projective plane

The line at infinity

$$\ell_\infty = (0, 0, 1)^T$$

The projective plane

The line at infinity

$$\ell_\infty = (0, 0, 1)^T$$

Comments:

- It is formed by the points of the plane $\pi_0 = \{(x_1, x_2, 0)^T : (x_1, x_2) \neq (0, 0)\}$.
- It satisfies $\langle (0, 0, 1)^T, (x_1, x_2, 0)^T \rangle = 0$.
- Intersection of ℓ_∞ and $\ell = (a, b, c)^T$: $\mathbf{x} = (b, -a, 0)^T$, point at infinity.

The projective plane

Conics are curves formed by the intersection of a cone with planes at different angles: the conic sections. These curves are: circles, ellipses, parabolas, and hyperbolas.

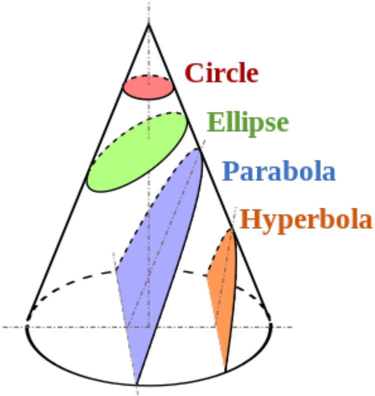


Image source: [Wikipedia]

The projective plane

2. Representation of conics:

Equation of a conic in the plane:

$$ax^2 + bxy + cy^2 + dx + ey + f = 0, \quad a, b, c, d, e, f \in \mathbb{R}.$$

Consider the symmetric matrix:

$$C = \begin{pmatrix} a & b/2 & d/2 \\ b/2 & c & e/2 \\ d/2 & e/2 & f \end{pmatrix}$$

For $\mathbf{x} = (x, y, 1)^T$, the conic equation writes:

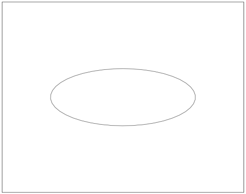
$$\langle C\mathbf{x}, \mathbf{x} \rangle = 0, \text{ or } \mathbf{x}^T C \mathbf{x} = 0$$

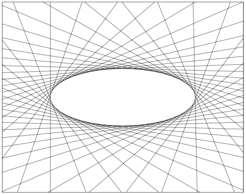
(Note: it holds also for $\mathbf{x}' = s\mathbf{x}$)
Equivalent representations: $C \equiv C'$, if $\exists k \neq 0$ such that $C' = kC$.

The projective plane

2. Representation of conics:

Dual conic (or line conic) There exists a conic that defines an equation for lines (duality points-lines).





Denoted by C^*. It verifies:

$$\langle C^*\ell, \ell\rangle = 0, \text{ or } \ell^T C^* \ell = 0$$

(Note: it holds also for $\ell' = s\ell$)
Equivalent representations: $C^* \equiv C^{*'}$, if $\exists k \neq 0$ such that $C^{*'} = kC^*$.
If C is invertible, then $C^* \equiv C^{-1}$
